### Address Bus (A1-A23)

This 23-bit, unidirectional, three-state bus is capable of addressing eight megawords of data. It provides the address for bus operation during all cycles except inter-

rupt cycles. During interrupt cycles, address lines A1, A2, and A3 provide information about what level interrupt is being serviced while address lines A4-A23 are all set to a logic high.

### Data Bus (D0-D15)

This 16-bit, bidirectional, three state bus is the general purpose data path. It can transfer and accept data in either word or byte length. During an interrupt acknowledge cycle, an external device supplies the interrupt vector on data lines D0-D7.

### Asynchronous Bus Control

Asynchronous data transfers are handled using the following control signals:

**Address Strobe (AS)** — This signal indicates that there is a valid address on the address bus.

### PIN CONFIGURATION<sup>1</sup>

**Read/Write (R/W)** — This signal defines the data bus transfer as a read or write cycle. The R/W signal also works in conjunction with the upper and lower data strobes as explained in the next paragraph.

**Upper and Lower Data Strobes (UDS, LDS)** — These signals control the data on the bus as shown in table 2. When the R/W line is high, the processor will read from the data bus as indicated. When the R/W line is low, the processor will write to the data bus as shown.

**Data Transfer Acknowledge (DTACK)** — This input indicates that the data transfer is completed. When the processor recognizes DTACK during a read cycle, data is latched and the bus cycle is terminated. When DTACK is recognized during a write cycle, the bus cycle is terminated. An active transition of DTACK indicates the termination of a data transfer on the bus.

If the system must run at a maximum rate determined by RAM access times, the relationship between the times at which DTACK and data are sampled is important. All control and data lines are sampled during the SCN68000's clock high time. The clock is internally buffered, which results in some slight differences in the sampling and recognition of various signals. The DTACK signal, like other control signals, is internally synchronized to allow for valid operation in an asynchronous system. If the required setup time (#47)<sup>1</sup> is met during S4, DTACK will be recognized during

TABLE 2 DATA STROBE CONTROL OF DATA BUS

UDS	LDS	R/W	D8-D15	D0-D7
High	High	-	No valid data	No valid data
Low	Low	High	Valid data bits 8-15	Valid data bits 0-7
High	Low	High	No valid data	Valid data bits 0-7
Low	High	High	Valid data bits 8-15	No valid data
Low	Low	Low	Valid data bits 8-15	Valid data bits 0-7
High	Low	Low	Valid data bits 0-7*	Valid data bits 0-7
Low	High	Low	Valid data bits 8-15	Valid data bits 8-15*

\*These conditions are a result of current implementation and may not appear on future devices.

S5 and S6, and data will be captured during S6. The data must meet the required setup time (#27). If an asynchronous control signal does not meet the required setup time, it is possible that it may not be recognized during that cycle. Because of this, asynchronous systems must not allow DTACK to precede data by more than parameter #31.

Asserting DTACK (or BERR) on the rising edge of a clock (such as S4) after the assertion of address strobe will allow an SCN68000 system to run at its maximum bus rate. If setup times #27 and #47 are guaranteed, #31 may be ignored.

### Bus Arbitration Control

These three signals form a bus arbitration circuit to determine which device will be the bus master device:

**Bus Request ( $\overline{BR}$ )** — This input is wire ORed with all other devices that could be bus masters. It indicates to the processor that some other device desires to become the bus master.

**Bus Grant ( $\overline{BG}$ )** — This output indicates to all other potential bus master devices that the processor will release bus control at the end of the current bus cycle.

**Bus Grant Acknowledge ( $\overline{BGACK}$ )** — This input indicates that some other device has become the bus master. This signal cannot be asserted until the following four conditions are met:

1. A bus grant has been received.
2. Address strobe is inactive, indicating that the microprocessor is not using the bus.

3. Data transfer acknowledge is inactive, indicating that another device is not using the bus.

4. Bus grant acknowledge is inactive, indicating that no other device is still claiming bus mastership.

### Interrupt Control ( $\overline{IPL0}, \overline{IPL1}, \overline{IPL2}$ )

These inputs indicate the encoded priority level of the device requesting an interrupt. Level seven is the highest priority while level zero indicates that no interrupts are requested. The least significant bit is given in  $\overline{IPL0}$  and the most significant bit is contained in  $\overline{IPL2}$ .

### System Control

The system control inputs are used to either reset or halt the processor and to indicate to the processor that bus errors have occurred.

**Bus Error ( $\overline{BERR}$ )** — This input informs the processor that there is a problem with the cycle currently being executed. Problems may be the result of nonresponding devices, interrupt vector acquisition failure, illegal access request as determined by a memory management unit, or other application dependent errors. The bus error signal interacts with the halt signal to determine if exception processing should be performed or the current bus cycle should be retried (see Bus Error and Halt Operation for additional information).

**Reset ( $\overline{RESET}$ )** — This bidirectional signal line acts to reset the processor (initiate a system initialization sequence) in response to an external reset signal. An in-

ternally generated reset (result of a RESET instruction) causes all external devices to be reset and the internal state of the processor is not affected. A total system reset (processor and external devices) is the result of external HALT and RESET signals applied at the same time (see Reset Operation for additional information).

**Halt ( $\overline{HALT}$ )** — When this bidirectional line is driven by an external device, it will cause the processor to stop at the completion of the current bus cycle. When the processor has been halted using this input, all control signals are inactive and all three-state lines are put in their high-impedance state. When the processor has stopped executing instructions, such as in a double bus fault condition, the halt line is driven by the processor to indicate to external devices that the processor has stopped (see Bus Error and Halt Operation for additional information).

### Peripheral Control

These control signals are used to allow the interfacing of synchronous peripheral devices with the asynchronous SCN68000:

**Enable (E)** — This signal is the enable signal for synchronous type peripheral devices. The period for this output is ten SCN68000 clock periods (six clocks low; four clocks high).

**Valid Peripheral Address ( $\overline{VPA}$ )** — This input indicates that the device or region addressed is a synchronous device and that data transfer should be synchronized with the enable (E) signal. This input also indicates that the processor should use automatic vectoring for an interrupt (see Interfacing with Synchronous Peripherals for additional information).

**Valid Memory Address ( $\overline{VMA}$ )** — This output is used to indicate to synchronous peripheral devices that there is a valid address on the address bus and the processor is synchronized to enable. This signal is issued only in response to a valid peripheral address (VPA) input which indicates that the peripheral is a synchronous device.

### Processor Status (FC0, FC1, FC2)

These function code outputs indicate the state (user or supervisor) and the cycle type currently being executed (see table 3). The information indicated by the function code is valid whenever address strobe (AS) is active.

Table 3 FUNCTION CODE OUTPUTS

FC2	FC1	FC0	Cycle Type
Low	Low	Low	(Undefined, Reserved)
Low	Low	High	User Data
Low	High	Low	User Program
Low	High	High	(Undefined, Reserved)
High	Low	Low	(Undefined, Reserved)
High	Low	High	Supervisor Data
High	High	Low	Supervisor Program

### Clock (CLK)

The clock input is a TTL-compatible signal that is internally buffered for development of the internal clocks needed by the processor. The clock input is a constant frequency.

**ジャンパー取替方法**

- IC2,3が600milタイプの場合  
A図の様にジャンパー線を接続する。その際、IC2,3に接続されるジャンパー線はICの足に直接半田付けしなければならないので、半田ブリッジの内容には注意すること。また、JP6,7の2本のジャンパー線は、半田橋からの取り外し可能です。
- IC2,3が300milタイプの場合  
A図の様にジャンパー線を接続する。尚、IC2,3に接続されるジャンパー線は、ICの外側の部品穴が未使用になるので、そこに半田付けすること。
